

Data wrangling

Raw to tidy data

Daniela Palleschi

2024-05-14

Learning objectives

Today we will...

- clean our first dataset
- implement literate programming principles
- use `dplyr` verbs to wrangle columns and rows
- save our tidy dataset

Review: Workflow

- let's first make sure we've got our project properly set-up

Workflow bare minimum

- self-contained project
 - everything available in one folder
 - e.g., RProjects
- README file
 - a markdown (.md) file
 - describing the folder/analysis structure
 - can be updated as you build the project

RProjects

- a folder containing
 - an `.RProj` file (which opens RStudio)
 - all folders/files required for a project
- `File > New Project > New Directory > New Project > New Project > Create Project`

README

- to create an `.md` file: `File > New File > Markdown File`
- create informative heading
 - describe project purpose
 - describe folders/scripts as they currently are
- save/Preview as `README.md` in the project folder

`here`

- `here` package
 - will always access the project folder
 - try running `here()` from within a project; what's the output?

Project folder structure

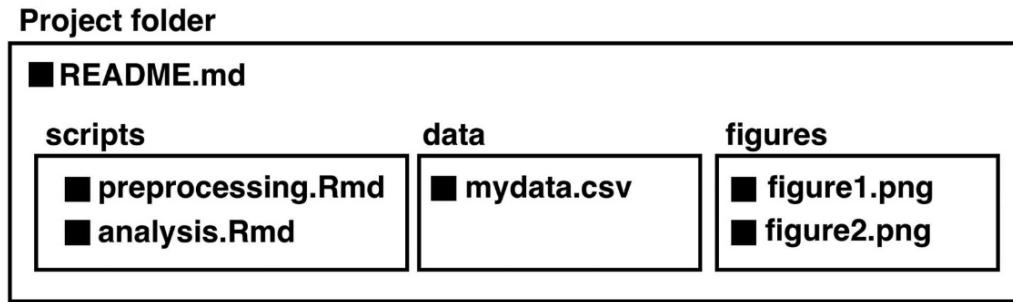

Figure 2.4. Folder structure for a data analysis project; black squares represent data files

Figure 1: Image source: Winter (2019)

Review: Reproducible code

- is located within a project
 - which also contains all relevant data/files
- runs linearly (from top to bottom)
 - loads all required packages at the top
 - uses file paths relative to its project
 - is created/edited after running `Session > Restart R`
- at the very least, ends with a section (e.g., `# Session Info`) containing `sessionInfo()`
 - but other options: `renv` package, `targets` package, `docker` for environment containers

Checklist

RProject

- `.RProj`
- `README.md`
- `data/`
- `scripts/` (for analyses)
- `notes/` (if for class notes)

Scripts (.qmd/.Rmd)

- load libraries at beginning
- chunks run linearly (top-to-bottom)
- script has helpful headings
- contains text to describe stream of thought
- code has helpful comments
- `sessionInfo()` at the end

Data cleaning

- or data wrangling, tidying, etc.
 - each can have a different specific meaning
 - but all refer to steps taken to tame raw/wild data

‘wrangle’ defined

/ ræŋ l/

noun

a dispute or argument, typically one that is long and complicated. “an insurance wrangle is holding up compensation payments”

verb

1. have a long, complicated dispute or argument. “the bureaucrats continue wrangling over the fine print”
2. NORTH AMERICAN round up, herd, or take charge of (livestock). “the horses were wrangled early”

Data Wrangling

- data wrangling = tidying + transforming
- an often long, arduous stage of analysis

Tidy

- re-shaping
 - e.g., from wide to long data

- outcome:
 - each column = a variable
 - each row = an observation

Transform

- filtering
- creating new variables based on observations (e.g., reaction times)
- computing summary statistics (e.g., means)

Why tidy data?

- helps future you
 - and collaborators
- facilitates sharing your data *and* code (Laurinavichyute et al., 2022)
- in short: facilitates reproducibility!

What does tidy data look like?

Three rules (Wickham et al., 2023):

1. Each variable is a column, each column is a variable
2. Each observation is a row, each row is an observation
3. Each value is a cell, each cell is a single value

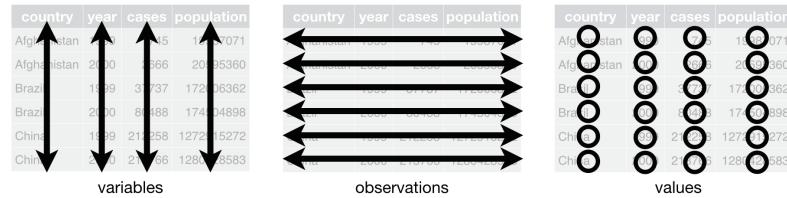

Figure 2: [Image source](#): Wickham et al. (2023) (all rights reserved)

- N.B., how you define a *variable* or *observation* is relative to what you want to do
 - for now, let's consider a single trial per participant as an observation

the tidyverse

- a collection of R packages for tidy data
- you need to load a package at the beginning of every session
 - today we will mostly use functions from the `dplyr` package
 - * if you load the `tidyverse` you don't need to also load `dplyr`

```
# load tidyverse  
library(tidyverse)
```

💡 package versions

- you can check the package version with:

```
packageVersion("tidyverse")
```

```
[1] '2.0.0'
```

- need to update?

```
# update a single package  
install.packages("tidyverse")
```

- what about your other packages?

```
# which packages need updating?  
old.packages()  
# update all old packages  
update.packages()
```

base R pipe |>

- takes the object before it and feeds it into the next command
 - the pipe could be read as “and then”
 - there's a useful shortcut: `Ctrl/Cmd+Shift+M`
 - N.B., pre-2023 the only pipe was `%>%` (`magrittr` package)

```
1 # take data frame and then...
2 iris |>
3   # print the head
4   head()
```

| | Sepal.Length | Sepal.Width | Petal.Length | Petal.Width | Species |
|---|--------------|-------------|--------------|-------------|---------|
| 1 | 5.1 | 3.5 | 1.4 | 0.2 | setosa |
| 2 | 4.9 | 3.0 | 1.4 | 0.2 | setosa |
| 3 | 4.7 | 3.2 | 1.3 | 0.2 | setosa |
| 4 | 4.6 | 3.1 | 1.5 | 0.2 | setosa |
| 5 | 5.0 | 3.6 | 1.4 | 0.2 | setosa |
| 6 | 5.4 | 3.9 | 1.7 | 0.4 | setosa |

Figure 3: Image source: [magitr documentation](#) (all rights reserved)

load our data

```
# load lifetime data
readr::read_csv(here::here("data/data_lifetime_pilot.csv"))
```

```
# A tibble: 4,431 x 28
  RECORDING_SESSION_LABEL TRIAL_INDEX EYE_USED IA_DWELL_TIME
  <chr>                  <dbl> <chr>           <dbl>
1 px3                     1     RIGHT            0
2 px3                     2     RIGHT            0
3 px3                     3     RIGHT            0
4 px3                     3     RIGHT            0
```

```

5 px3          3 RIGHT      0
6 px3          3 RIGHT      0
7 px3          3 RIGHT      0
8 px3          3 RIGHT      0
9 px3          4 RIGHT      0
10 px3         5 RIGHT      0
# i 4,421 more rows
# i 24 more variables: IA_FIRST_FIXATION_DURATION <dbl>,
#   IA_FIRST_RUN_DWELL_TIME <dbl>, IA_FIXATION_COUNT <dbl>, IA_ID <dbl>,
#   IA_LABEL <chr>, IA_REGRESSION_IN <dbl>, IA_REGRESSION_IN_COUNT <dbl>,
#   IA_REGRESSION_OUT <dbl>, IA_REGRESSION_OUT_COUNT <dbl>,
#   IA_REGRESSION_PATH_DURATION <dbl>, KeyPress <dbl>, rt <dbl>, bio <chr>,
#   critical <chr>, gender <chr>, item_id <dbl>, list <dbl>, match <chr>, ...

```

- was anything added to the Environment pane (top right box in RStudio)?

variable assignment with <-

- object_name <- code_output_to_be_saved_as_object_name

```

1 # load lifetime data and store it under df_lifetime
2 df_lifetime <- readr::read_csv(here::here("data/data_lifetime_pilot.csv"),
3                               # for special characters
4                               locale = readr::locale(encoding = "latin1")
5 )

```

- you should now see the object `df_lifetime` in the Environment pane

A note on annotation

- annotate as you go: provide useful comments to describe your code (`# comment`)
- you always have at least one collaborator: future you!
 - comments

First we load required libraries.

```

1 # load libraries
2 library(tidyverse) # for e.g., wrangling and plotting
3 library(here) # for file-paths relative to project folder

```

Tidyverse verbs

- verbs are functions from the `tidyverse` package
- for data tidying and transforming we'll mostly use verbs from the `dplyr` package, which is part of the `tidyverse`
- check out [RLadies Freiburg](#) to see a [YouTube video](#) that covers most of these verbs

Wrangling columns

`rename()`

- one of the first things you'll often want to do is rename some variables
- let's start by re-naming some of our variables
 - e.g., `RECORDING_SESSION_LABEL` is a long way of saying 'participant'

```
1 # rename variables
2 df_lifetime <- df_lifetime |> # make df_lifetime from df_lifetime BUT THEN
3   rename("px" = RECORDING_SESSION_LABEL, # rename a variable and (comma = 'and')
4         "trial" = TRIAL_INDEX) # another variable
```

Exercise

Change the following names:

- `EYE_USED` to `eye`
- `IA_DWELL_TIME` to `tt`
- `IA_FIRST_FIXATION_DURATION` to `ff`
- `IA_FIXATION_COUNT` to `fix_count`
- `IA_FIRST_RUN_DWELL_TIME` to `fp`
- `IA_ID` to `region_n`
- `IA_LABEL` to `region_text`
- `IA_REGRESSION_IN` to `reg_in`
- `IA_REGRESSION_IN_COUNT` to `reg_in_count`
- `IA_REGRESSION_OUT` to `reg_out`
- `IA_REGRESSION_OUT_COUNT` to `reg_out_count`
- `IA_REGRESSION_PATH_DURATION` to `rpd`
- `name_vital_status` to `lifetime`

```
# the names should then look like this:  
names(df_lifetime)
```

```
[1] "px"           "trial"        "eye"          "tt"  
[5] "ff"           "fp"            "fix_count"    "region_n"  
[9] "region_text"  "reg_in"       "reg_in_count" "reg_out"  
[13] "reg_out_count" "rpd"         "KeyPress"     "rt"  
[17] "bio"          "critical"     "gender"       "item_id"  
[21] "list"         "match"        "condition"   "name"  
[25] "lifetime"     "tense"        "type"         "yes_press"
```

relocate

- the second thing you might want to do is reorder your variables so the most important/relevant are near the beginning and ordered logically
 - let's order our continuous reading time variables from 'earliest' to 'latest' measure

```
df_lifetime <- df_lifetime |>  
  relocate(ff,fp,rpd,tt, .after="eye") |>  
  relocate(region_n, region_text, .after="trial")
```

```
names(df_lifetime[1:10])
```

```
[1] "px"           "trial"        "region_n"      "region_text"  "eye"  
[6] "ff"           "fp"            "rpd"          "tt"           "fix_count"
```

mutate()

Mutate column(s):

- new columns

```
1 df_lifetime <- df_lifetime |>  
2   mutate(new_column = "new")
```

- what will `new_column` contain?

```
df_lifetime |>
  select(px, new_column, trial) |>
  head()
```

```
# A tibble: 6 x 3
  px      new_column trial
  <chr>   <chr>       <dbl>
1 px3     new           1
2 px3     new           2
3 px3     new           3
4 px3     new           3
5 px3     new           3
6 px3     new           3
```

- change existing column

```
1 df_lifetime <- df_lifetime |>
2   mutate(new_column = px,
3         trial = trial + 5)
```

- what will `new_column` and `trial` contain?

```
df_lifetime |>
  select(px, new_column, trial) |>
  head()
```

```
# A tibble: 6 x 3
  px      new_column trial
  <chr>   <chr>       <dbl>
1 px3     px3          6
2 px3     px3          7
3 px3     px3          8
4 px3     px3          8
5 px3     px3          8
6 px3     px3          8
```

- but let's undo that...

```
1 df_lifetime <- df_lifetime |>
2   mutate(trial = trial - 5)
```

- what will `trial` contain?

```
df_lifetime |>
  select(px, new_column, trial) |>
  head()
```

```
# A tibble: 6 x 3
  px    new_column trial
  <chr> <chr>      <dbl>
1 px3   px3        1
2 px3   px3        2
3 px3   px3        3
4 px3   px3        3
5 px3   px3        3
6 px3   px3        3
```

if_else()

- can be used e.g., inside `mutate()`
 - change values based on some logical condition
 - can be used to change an existing column, or create a new one
- `ifelse(condition, output_if_true, output_if_false)`

```
1 df_lifetime <- df_lifetime |>
2   mutate(new_column = if_else(name=="Aaliyah","name is Aaliyah","name is not Aaliyah"))
```

💡 Logical operators

- symbols used to describe a logical condition
- `==` is identical (`1 == 1`)
- `!=` is not identical (`1 != 2`)
- `>` is greater than (`2 > 1`)
- `<` is less than (`1 < 2`)
- `&` and also (for multiple conditions)
- `|` or (for multiple conditions)

case_when()

- can be used e.g., inside `mutate()`
 - change values based on multiple logical conditions
 - for cases too complex for `ifelse()`
 - can be used to change an existing column, or create a new one
- `case_when(condition & other_condition | other_condition ~ output, TRUE ~ output_otherwise)`
 - if you don't include `TRUE ~ output` then NAs will be created

```
1 df_lifetime <- df_lifetime |>
2   mutate(newer_column = case_when(
3     name=="Aaliyah" & trial > 104 ~ "Aaliyah 2nd half",
4     name=="Beyoncé" & (px == "px01" | px == "px04") ~ "Beyoncé px04 or px06",
5     TRUE ~ "otherwise"))
```

Exercise

1. Create a new variable `accept` that checks whether the button pressed (`KeyPress`) equals the button that corresponds to an acceptance (`yes_press`)
 - if `KeyPress` and `yes_press` are the same, `accept` should be 1. If not, `accept` should be 0
 - hint: you will need `if_else()` or `case_when()`
2. Create a new variable `accuracy` where:
 - if `match` is yes and `accept` is 1, `accuracy` is 1
 - if `match` is no and `accept` is 0, `accuracy` is 1
 - if `match` is yes and `accept` is 0, `accuracy` is 0
 - if `match` is no and `accept` is 1, `accuracy` is 0
- if correct, the means and summaries should look like this:

```
mean(df_lifetime$accept)
```

```
[1] 0.6068608
```

```
summary(as_factor(df_lifetime$accept))
```

```
0      1  
1742 2689
```

```
mean(df_lifetime$accuracy)
```

```
[1] 0.6267208
```

```
summary(as_factor(df_lifetime$accuracy))
```

```
0      1  
1654 2777
```

Extra exercise

3. Create a new variable `region`, that has the following values based on `region_n`

- `region_n` 1 is region verb-1
- `region_n` 2 is region verb
- `region_n` 3 is region verb+1
- `region_n` 4 is region verb+2
- `region_n` 5 is region verb+3
- `region_n` 6 is region verb+4

```
summary(as_factor(df_lifetime$region))
```

```
filler verb-1    verb verb+1 verb+2 verb+3 verb+4  
1024      639      639      639      639      212
```

4. Now relocate our new variables so that:

- `region` is before `region_n`
- `KeyPress` is after `yes_press`

```
names(df_lifetime)
```

```
[1] "px"           "trial"        "region"        "region_n"
[5] "region_text"  "eye"          "ff"            "fp"
[9] "rpd"          "tt"           "fix_count"     "reg_in"
[13] "reg_in_count" "reg_out"      "reg_out_count" "rt"
[17] "bio"          "critical"    "gender"        "item_id"
[21] "list"         "match"        "condition"    "name"
[25] "lifetime"     "tense"        "type"          "yes_press"
[29] "KeyPress"     "new_column"   "newer_column"  "accept"
[33] "accuracy"
```

group_by() and ungroup()

Group data by certain variable(s)

- then perform some mutation
- then ungroup the data

```
df_lifetime <- df_lifetime |>
  group_by(px) |>
  mutate(px_accuracy = mean(accuracy)) |>
  ungroup()
```

```
round(
  range(df_lifetime$px_accuracy),
  2)
```

```
[1] 0.26 0.90
```

.by

- `mutate()` also takes `.by` = as an argument
 - does the same thing as `group_by()/ungroup()`
 - as of `dplyr 1.1.0` version ([more info](#))

```
df_lifetime <- df_lifetime |>
  mutate(px_accuracy = mean(accuracy),
        .by = px)
```

```
round(  
  range(df_lifetime$px_accuracy),  
  2)
```

```
[1] 0.26 0.90
```

separate()

- create new columns from a single column

```
df_lifetime <- df_lifetime |>  
  separate(name,  
    sep = " ",  
    into = c("First", "Last"),  
    remove = F, # don't remove original column (name)  
    extra = "merge") # if extra chunks, combine in 'Last' (von der...)
```

- opposite: unite()

select()

- keep only certain column(s)
- often used to preview changes
- if result is saved as an object (<-) will remove all other columns
 - so be careful when saving as an already existing object (e.g., df <- df |> select(...))

```
df_lifetime |>  
  select(px) |> head(10)
```

```
# A tibble: 10 x 1  
  px  
  <chr>  
1 px3  
2 px3  
3 px3  
4 px3  
5 px3  
6 px3
```

```

7 px3
8 px3
9 px3
10 px3

df_lifetime |>
  select(px, trial) |> head(10)

```

A tibble: 10 x 2

| px | trial |
|--------|-------|
| <chr> | <dbl> |
| 1 px3 | 1 |
| 2 px3 | 2 |
| 3 px3 | 3 |
| 4 px3 | 3 |
| 5 px3 | 3 |
| 6 px3 | 3 |
| 7 px3 | 3 |
| 8 px3 | 3 |
| 9 px3 | 4 |
| 10 px3 | 5 |

`select(-)`

- or remove certain columns

```

df_lifetime |>
  select(-px, -trial) |> head(10)

```

A tibble: 10 x 34

| | region | region_n | region_text | eye | ff | fp | rpd | tt | fix_count | reg_in |
|---|--------|----------|----------------|-------|-------|-------|-------|-------|-----------|--------|
| | <chr> | <dbl> | <chr> | <chr> | <dbl> | <dbl> | <dbl> | <dbl> | <dbl> | <dbl> |
| 1 | filler | 1 | He owned innu~ | RIGHT | 0 | 0 | 0 | 0 | 0 | 0 |
| 2 | filler | 1 | She is a moth~ | RIGHT | 0 | 0 | 0 | 0 | 0 | 0 |
| 3 | verb-1 | 1 | She | RIGHT | 0 | 0 | 0 | 0 | 0 | 0 |
| 4 | verb | 2 | will perform | RIGHT | 0 | 0 | 0 | 0 | 0 | 0 |
| 5 | verb+1 | 3 | in prestigiou~ | RIGHT | 0 | 0 | 0 | 0 | 0 | 0 |
| 6 | verb+2 | 4 | in the future, | RIGHT | 0 | 0 | 0 | 0 | 0 | 0 |
| 7 | verb+3 | 5 | as reported i~ | RIGHT | 0 | 0 | 0 | 0 | 0 | 0 |
| 8 | verb+4 | 6 | as reported i~ | RIGHT | 0 | 0 | 0 | 0 | 0 | 0 |

```

9 filler      1 He interviewe~ RIGHT      0      0      0      0      0      0
10 verb-1     1 She          RIGHT      0      0      0      0      0      0
# i 24 more variables: reg_in_count <dbl>, reg_out <dbl>, reg_out_count <dbl>,
#   rt <dbl>, bio <chr>, critical <chr>, gender <chr>, item_id <dbl>,
#   list <dbl>, match <chr>, condition <chr>, name <chr>, First <chr>,
#   Last <chr>, lifetime <chr>, tense <chr>, type <chr>, yes_press <dbl>,
#   KeyPress <dbl>, new_column <chr>, newer_column <chr>, accept <dbl>,
#   accuracy <dbl>, px_accuracy <dbl>

```

💡 Select criteria

You can also use criteria for `select`:

- `select(starts_with("x"))` select columns that start with a character string
- `select(ends_with("x"))` select columns that end with a character string
- `select(contains("x"))` select columns that contain a character string
- `select(num_range("prefix", 10:20))` select columns with a `prefix` followed by a range of values

Exercise

Remove the example variables we created with `mutate`:

- `new_column`, `newer_column`, `First`, `Last`

```
# should look like this after
names(df_lifetime)
```

```

[1] "px"           "trial"        "region"       "region_n"
[5] "region_text"  "eye"          "ff"           "fp"

```

Wrangling rows

```
filter()
```

- select certain rows based on certain criteria
 - requires logical operators (==, !=, >, <, |)
 - N.B. when testing logical conditions == is needed

```
1 df_lifetime |>
2   filter(trial == 1)

# A tibble: 8 x 32
  px      trial region region_n region_text          eye    ff    fp    rpd    tt
  <chr> <dbl> <chr>     <dbl> <chr>          <chr> <dbl> <dbl> <dbl> <dbl>
1 px3       1 filler        1 He owned innumerabl~ RIGHT     0     0     0     0
2 px5       1 filler        1 She is a mother of ~ RIGHT    145  1603  1603  1603
3 px6       1 filler        1 He is a father of t~ RIGHT    147  1224  1224  1224
4 px2       1 filler        1 She made innumerabl~ RIGHT     84   1829  1829  1829
5 px7       1 filler        1 In the '70s, he own~ RIGHT    138  2456  2456  2456
6 px1       1 filler        1 Beloved morning sho~ RIGHT    160  1708  1708  1708
7 px8       1 filler        1 She was a mother of~ RIGHT    220  806   806   806
8 px4       1 filler        1 In the '70s, he own~ LEFT     171  3557  3557  3557
# i 22 more variables: fix_count <dbl>, reg_in <dbl>, reg_in_count <dbl>,
#   reg_out <dbl>, reg_out_count <dbl>, rt <dbl>, bio <chr>, critical <chr>,
#   gender <chr>, item_id <dbl>, list <dbl>, match <chr>, condition <chr>,
#   name <chr>, lifetime <chr>, tense <chr>, type <chr>, yes_press <dbl>,
#   KeyPress <dbl>, accept <dbl>, accuracy <dbl>, px_accuracy <dbl>
```

```
filter()
```

What are these code chunks doing?

```
1 df_lifetime |>
2   filter(px_accuracy > .5)

1 df_lifetime |>
2   filter(px == "px3")
```

```
1 df_lifetime |>  
2   filter(px == "px3" | trial == "3")
```

```
1 df_lifetime |>  
2   filter(px == "px3" & trial != "3")
```

Exercise

1. Create a new dataframe `df_crit` that includes only critical trials
2. Create a new dataframe `df_fill` that includes only filler trials
 - Tip: trial type is stored in the column `type`

```
df_crit |> select(type) |> head()
```

```
# A tibble: 6 x 1  
  type  
  <chr>  
1 critical  
2 critical  
3 critical  
4 critical  
5 critical  
6 critical
```

```
df_fill |> select(type) |> head()
```

```
# A tibble: 6 x 1  
  type  
  <chr>  
1 filler  
2 filler  
3 filler  
4 filler  
5 filler  
6 filler
```

`distinct()`

- like `filter()`, but for *distinct values* of a variable
 - “select rows with distinct values for some row(s)”

```
1 df_crit |>
2   distinct(px)
```

```
# A tibble: 8 x 1
  px
  <chr>
1 px3
2 px5
3 px6
4 px2
5 px7
6 px1
7 px8
8 px4
```

```
1 df_crit |>
2   distinct(px, name)
```

```
# A tibble: 639 x 2
  px      name
  <chr> <chr>
1 px3    Edith Piaf
2 px3    Aaliyah
3 px3    David Beckham
4 px3    Jana Novotna
5 px3    Grace Kelly
6 px3    Nigella Lawson
7 px3    Coco Chanel
8 px3    Ben Kingsley
9 px3    Jim Carrey
10 px3   Judy Garland
# i 629 more rows
```

```
1 df_crit |>
2   distinct(px, name,
3             .keep_all=T)
```

```

# A tibble: 639 x 32
  px      trial region region_n region_text eye      ff      fp      rpd      tt
  <chr> <dbl> <chr>     <dbl> <chr>      <chr> <dbl> <dbl> <dbl> <dbl>
1 px3      3 verb-1      1 She      RIGHT    0      0      0      0
2 px3      5 verb-1      1 She      RIGHT    0      0      0      0
3 px3      8 verb-1      1 He       RIGHT    0      0      0      0
4 px3     10 verb-1      1 She      RIGHT    0      0      0      0
5 px3     13 verb-1      1 She      RIGHT    0      0      0      0
6 px3     16 verb-1      1 She      RIGHT    0      0      0      0
7 px3     18 verb-1      1 She      RIGHT    0      0      0      0
8 px3     21 verb-1      1 He       RIGHT    0      0      0      0
9 px3     23 verb-1      1 He       RIGHT    0      0      0      0
10 px3    26 verb-1      1 She      RIGHT   0      0      0      0
# i 629 more rows
# i 22 more variables: fix_count <dbl>, reg_in <dbl>, reg_in_count <dbl>,
#   reg_out <dbl>, reg_out_count <dbl>, rt <dbl>, bio <chr>, critical <chr>,
#   gender <chr>, item_id <dbl>, list <dbl>, match <chr>, condition <chr>,
#   name <chr>, lifetime <chr>, tense <chr>, type <chr>, yes_press <dbl>,
#   KeyPress <dbl>, accept <dbl>, accuracy <dbl>, px_accuracy <dbl>

```

`arrange()`

- sort column(s) in ascending or descending order
 - this is really just for ease of reading

```

# default: ascending order (A-Z)
df_crit |>
  distinct(px, trial, name, condition) |>
  arrange(px, trial)

```

```

# A tibble: 639 x 4
  px      trial name           condition
  <chr> <dbl> <chr>          <chr>
1 px1      3 Amy Winehouse deadPP
2 px1      5 John Wayne    deadPP
3 px1      8 Abraham Lincoln deadPP
4 px1     10 Helen Mirren  livingSF
5 px1     13 Paul McCartney livingSF
6 px1     16 Ariana Grande livingPP
7 px1     18 Kate Middleton livingSF
8 px1     21 Johan Cruyff   deadSF

```

```

9 px1      23 Marilyn Monroe  deadPP
10 px1     26 Biggie Smalls  deadSF
# i 629 more rows

# descending order (Z-A)
df_crit |>
  distinct(px, trial, name, condition) |>
  arrange(desc(px), trial)

# A tibble: 639 x 4
  px    trial name          condition
  <chr> <dbl> <chr>        <chr>
1 px8     3 Whitney Houston deadPP
2 px8     5 Elton John    livingSF
3 px8     8 Jackie Chan   livingPP
4 px8    10 Romy Schneider deadPP
5 px8    13 James Cameron livingSF
6 px8    16 Ella Fitzgerald deadSF
7 px8    18 Kathryn Hepburn deadPP
8 px8    21 Kate Middleton livingPP
9 px8    23 Janis Joplin   deadPP
10 px8   26 Serena Williams livingSF
# i 629 more rows

```

Save your tidy data

- once your data is nice and tidy, save it with a **new filename**
 - this way you always have the same starting point for your data exploration/analyses

```
# run this manually!
write.csv(df_lifetime, here::here("data/tidy_data_lifetime_pilot.csv"), row.names=FALSE)
```

Important terms

| | |
|----------------|---|
| wrangle | have a long dispute |
| data wrangling | tidying and transforming your data |
| tidy data | data where each column is a variable and each row is an observation |

| | |
|--|--|
| the tidyverse | a group of packages for tidy data |
| dplyr | a package within the tidyverse for data wrangling |
| pipe operator (<code> ></code> or <code> ></code>) | operational function, passes the result of one function/argument to the next |
| logical operators | compare values of two arguments: <code>&</code> , <code> </code> , <code>==</code> , <code>!=</code> , <code>></code> , <code><</code> |

Important functions

| | |
|-----------------------------|---|
| <code>read_csv()</code> | read-in a csv as a tibble (from <code>readr</code> package) |
| <code>rename()</code> | rename variables |
| <code>relocate()</code> | move variables |
| <code>mutate()</code> | change or create new variables |
| <code>if_else()</code> | condition for ‘ <code>mutate()</code> ’ |
| <code>case_when()</code> | handle multiple conditions for ‘ <code>mutate()</code> ’ |
| <code>group_by()</code> | group by a certain variable |
| <code>select()</code> | keep (or exclude) certain variables |
| <code>filter()</code> | keep (or exclude) rows based on some criteria |
| <code>distinct()</code> | keep rows with distinct value of given variable(s) |
| <code>arrange()</code> | sort variable(s) in ascending or descending order |
| <code>separate()</code> | split a variable into multiple variables |
| <code>pivot_longer()</code> | make wide data longer |
| <code>pivot_wider()</code> | make long data wider |
